Rajasekaran, *Computer Algorithms*

### 3 Maximum Selection

- Problem : Given  $n$  numbers,  $x_1, x_2, \dots, x_n$ . Find the largest number.
- Algorithm :  $O(1)$  CRCW algorithm; use  $n^2$  CPUs; assume all numbers are distinct

Step 1: For each CPU <sub>$i,j$</sub>  (for each  $1 \leq i, j \leq n$ ) in parallel :

$M_{i,j} = 1$  if  $x_i < x_j$ ; otherwise, 0

Step 2: For each row, use  $n$  CPUs to compute OR of  $n$  elements

Step 3: (cont. from step 2) If  $i^{\text{th}}$  row is 0, return  $x_i$ .

- Example : input  $\langle 3 \ 1 \ 4 \ 5 \ 2 \rangle$

After Step 1 : Matrix M

INDEX	1	2	3	4	5
1	0	0	1	1	0
2	1	0	1	1	1
3	0	0	0	1	0
4	0	0	0	0	0
5	1	0	1	1	0

After Step 2 : Row 4 return 0

After Step 3 : return maximum value 5

- Analysis

Total running time :  $O(1)$

Total work :  $n^2 * O(1) = O(n^2)$

Sequential Algorithm :  $O(n)$

It is not work optimal!

Recursive Algorithm :  $O(\log \log n)$  CRCW algorithm; use  $n$  CPUs;

Assume  $n$  is always a perfect square, i.e.  $k^2 = n$  (or  $k = n^{1/2}$ ).

If this is not true, take the smallest  $k$  such that  $k^2 \geq n$

Step 1: If  $n = 1$ , return  $x_1$

Step 2: Partition  $n$  elements &  $n$  processors  
into  $k$  groups, say,

$G_1, G_2, \dots, G_k$  (assume  $k^2 = n$ ).

In parallel, call the algorithm recursively to  
find maximum element  $m_i$  of each group  $G_i$

Step 3: Use previous algorithm with  $n$  CPUs to find  
the maximum of  $m_1, m_2, \dots, m_k$

CS535 Parallel Algorithms  
YOUNG

Part 2

5

- Analysis

This algorithm uses divide and conquer strategy

In step 2, each sub problem has size  $k$  or  $n^{1/2}$

( $n^{1/2}$  processors &  $n^{1/2}$  elements)

In step 3, the running time is  $O(1)$

WLOG, we assume that  $n = 2^{2^q}$  and  $T(2) = O(1)$ .

The total running time  $T(n)$  satisfy the recurrence

$$\begin{cases} T(n) = T(n^{1/2}) + O(1) \\ T(2) = O(1) \end{cases}$$

which solves to  $T(n) = (\log \log n)$

CS535 Parallel Algorithms  
YOUNG

Part 2

6

$$\begin{aligned}
T(n) &= T(n^{1/2}) + O(1) \\
&= (T(n^{1/4}) + O(1)) + O(1) \\
&= ((T(n^{1/8}) + O(1)) + O(1)) + O(1) \\
&= \dots \\
&= T(n^{1/2^{**}i}) + i \times O(1) \text{ (after } i \text{ steps)} \\
&= \dots \\
&= T(n^{1/2^{**}q}) + q \times O(1) \\
&= T(2) + q \times O(1) \\
&= O(1) + q \times O(1) \\
&= O(q) \\
&= O(\log \log n)
\end{aligned}$$

Note:  $n = 2^{2^q}$

$$\Rightarrow 2^q = \log n$$

$$\Rightarrow q = \log \log n$$

Total work :  $n * O(\log \log n) = O(n \log \log n)$

It is still not work optimal!

Part 2

7

## 4 Merging

- Problem : Given 2 sorted sequences  $X_1 = k_1, k_2, \dots, k_m$  and  $X_2 = k_{m+1}, k_{m+2}, \dots, k_{2m}$ .

Assume each sequence has  $m$  distinct elements, and  $m$  is an integral power of 2.

The goal is to produce a sorted sequence of  $2m$  elements.

- Best sequential algorithm is  $O(m)$

CS535 Parallel Algorithms  
YOUNG

Part 2

8

- For each  $k_j \in X_1$ , we know that it is the rank  $\#j$  element in  $X_1$ . We allocate a single processor to perform a binary search on  $X_2$  and figure out  $q$  (the number of elements in  $X_2$  that are less than  $k_j$ ). Then we know that  $k_j$  is the rank  $\#(j+q)$  element in  $X_1 \cup X_2$ .
- For each element in  $X_2$ , a similar procedure can be used to compute its rank in  $X_1 \cup X_2$ .
- We can use  $2m$  processors, one for each element. An overall rank can be found for each element using binary search in  $O(\log m)$  time. Merging can be done in  $O(\log m)$  time. **It is not work optimal!**

Theorem: Merging of two sorted sequences each of length  $m$  can be completed in  $O(\log m)$  time using  $m$  CREW PRAM processors.

CS535 Parallel Algorithms  
YOUNG

Part 2

9

- Recursive EREW Algorithm : Odd-Even Merge – using  $2m$  processors

#### Algorithm A

Step 1: If  $m=1$ , merge two sequence with 1 comparison

Step 2: Partition  $X_1$  into their odd and even parts,

i.e.  $X_1^{\text{odd}} = k_1, k_3, k_5, \dots, k_{m-1}$  and  $X_1^{\text{even}} = k_2, k_4, \dots, k_m$

Similarly, partition  $X_2$  into  $X_2^{\text{odd}}$  and  $X_2^{\text{even}}$

CS535 Parallel Algorithms  
YOUNG

Part 2

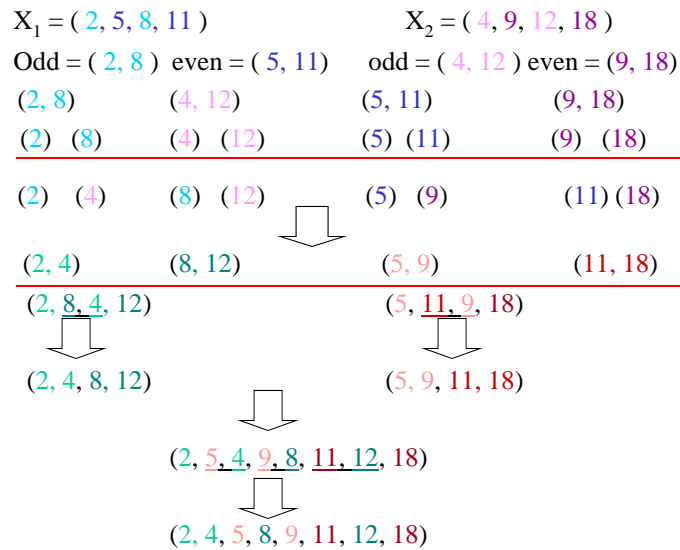

10

Step 3: Recursively merge  $X_1^{\text{odd}}, X_2^{\text{odd}}$  (and  $X_1^{\text{even}}, X_2^{\text{even}}$ ) using  $m$  processors.

Let  $L_1 = u_1, u_2, \dots, u_m$   
 $(L_2 = u_{m+1}, u_{m+2}, \dots, u_{2m})$   
 be the result.

Step 4: Form a sequence  $L = u_1, u_{m+1}, u_2,$   
 $u_{m+2}, u_3, u_{m+3}, \dots, u_m, u_{2m}$   
 Compare every pair  $(u_{m+i}, u_{1+i})$ ,  
 i.e.  $(u_{m+1}, u_2), (u_{m+2}, u_3), \dots$   
 Interchange elements if they are out of order.  
 Output the resultant sequence.

- Example :  $m = 4$

Theorem : The previous algorithm A correctly merge two sorted sequences of arbitrary numbers (Proof: Assignment #1)

- Analysis

This algorithm A uses divide and conquer strategy

Step 1,  $O(1)$

Step 2, Partition can be done by  $2m$  CPUs at the same time in  $O(1)$

Step 3, There are two sub-problems. Using  $m$  CPUs in parallel to solve each sub-problem. A sub-problem has 2 sorted lists and a list is with  $m/2$  elements.

Step 4, Using  $m$  CPUs in parallel in  $O(1)$

The total running time is

$$T(m) = T(m/2) + O(1) \Rightarrow T(m) = O(\log m)$$

Note :  $T(m)$  means running time to merge 2 sorted lists, each with  $m$  elements

$$\text{Total work} : 2m * O(\log m) = O(m \log m)$$

It is not work optimal!

- A work optimal CREW merging algorithm
- Goal : use  $O(m/\log m)$  CPUs to obtain  $O(\log m)$  algorithm

### Algorithm B

Step 1: Partition  $X_1$  in  $(m/\log m)$  parts,

$A_1, A_2, \dots, A_z$ ,

where  $z = (m/\log m)$ .

Note : each  $A_i$  has  $(\log m)$  elements.

CS535 Parallel Algorithms  
YOUNG

Part 2

15

Step 2: Let  $u_i$  be the largest element in  $A_i$ ,  
i.e. last element of  $A_i$ .

Assign a cpu to each  $u_i$ . Use binary search,  $O(\log m)$ , to search the correct position of  $u_i$  in  $X_2$ . This divides  $X_2$  into  $z$  parts  $B_1, B_2, \dots, B_z$ .

Now : we only need to merge  $A_i$  with  $B_i$  for  $1 \leq i \leq z$

CS535 Parallel Algorithms  
YOUNG

Part 2

16

Step 3 : If  $|B_i| = O(\log m)$ , then  $A_i$  and  $B_i$   
 can be merged in  $O(\log m)$ ;  
 Otherwise, partition  $B_i$  in  $\lceil (|B_i|/(\log m)) \rceil$  parts.  
 Now, use similar strategy as Step 2,  
 i.e. assign a cpu to each sub-part of  $B_i$ ,  
 use largest key to find correct  
 position in  $A_i$ , i.e.  $O(\log \log m)$ .  
 There are at most  $2z$  parts in  
 $B_1, B_2, \dots, B_z$ , (think about WHY?)  
 and each part has at most  $\log m$  elements.  
 We need at most  $2z$  CPUs, each pair needs  
 $O(\log m)$  to merge.

The total running time of Algorithm B  
 is  $O(\log m)$

Total work :

$$2(m/\log m) * O(\log m) = O(m)$$

It is work optimal!

## 5 Sorting

Odd Even Merge Sort :

### Algorithm C

- Step 1 : If  $n \leq 1$  return  $X$
- Step 2 : Use  $n$  CPUs to partition input  $X$  of  $n$  elements into 2 lists,  $X_1$  and  $X_2$ . Each with  $n/2$  elements
- Step 3: Use  $n/2$  CPUs to sort  $X_1$  recursively and  $n/2$  CPUs to sort  $X_2$  recursively.  
Let  $X_1^*$  and  $X_2^*$  be the result sorted lists.
- Step 4: Use Odd-Even merge to merge two sorted lists using  $n$  CPUs.

CS535 Parallel Algorithms  
YOUNG

Part 2

19

Analysis of Algorithm C :

**EREW** algorithm using  $n$  CPUs

$$T(n) = O(1) + T(n/2) + O(\log n)$$

$$= \log(n) + \log(n/2) + \log(n/4) + \dots + \log(n/2^i) ; i = \log n$$

$$= \log(n) + [\log(n) - \log 2] + [\log(n) - \log 4] + \dots + [\log(n) - \log(n)]$$

$$\leq \log(n) * \log(n)$$

$$T(n) = O(\log^2 n)$$

Total work  $O(n \log^2 n)$

It is not work optimal
